STELLA MARE PLATFORM

Press Kit

EUROPEAN SPINY LOBSTER (*PALINURUS ELEPHAS*) THE STELLA MARE PLATFORM (UNIVERSITY OF CORSICA / CNRS) IS ONE OF THE THREE LABORATORIES IN THE WORLD TO HAVE RAISED JUVENILES.

- A MAJOR SCIENTIFIC BREAKTHROUGH -

With 10 years of experience in controlling the reproduction of vulnerable species, the team of researchers and engineers from the University of Corsica and the CNRS (National Center for Scientific Research) has achieved the scientific and technical prowess of controlling European spiny lobster reproduction.

After the European flat oyster, the European lobster, the purple sea urchin, the dentin and the corb, it is towards the control of the reproduction of the European spiny lobster that the efforts of Stella Mare have been concentrated.

The first larval experiment with European spiny lobster, which had just started in early 2021, was successful in less than 3 months:

- 6 juvenile lobsters were obtained (83 days after hatching from the eggs)
- an encouraging survival rate of 50% was observed at the last larval stage (43 days after hatching).

It is necessary to remove several technological obstacles to the breeding of this species in order to control its reproduction. The complexity is due to the number and fragility of the larval stages, the length of rearing, the feed and the sanitary constraints of the process.

This is a major scientific breakthrough, having an ecological, economic and heritage impact for Corsica and beyond.

The European spiny lobster *Palinurus elephas* is observed in the North-East Atlantic Ocean (from Norway to Mauritania) but especially in the Mediterranean. In its southern distribution, it is observed from North Africa to Morocco, the Canary Islands and the Azores.

Classified as a « vulnerable species », it is on the Red List of Threatened Species by the International Union for the Conservation of Nature (IUCN). The European spiny lobster is also listed in appendices III of the Barcelona convention (list of species whose exploitation is regulated) and of the Bern convention (protected fauna species).

Its high selling price (50 to 100 € / kg) results from a relative scarcity confirmed by the continuous decline in catches recorded in the various fisheries of the European Union (from 1,100 tonnes in 1969 to 434 tonnes in 2017). In France, on the Atlantic coast, fishing increased from 1000 tonnes / year in the 1950s to 25 tonnes in 2010 *; in Scotland, from 271 tonnes in 1959 to 20 tonnes in 2010; in Portugal, from 400 tonnes / year in 1990-1992 to 12 tonnes in 2006-2007. Ecologically, a vicious circle has clearly set in. The scarcity of the resource has led to an increase in fishing effort (longer nets, more boats, deeper fishing,...etc.) and a repercussion on the whole of biodiversity with the increase in bycatch and of the impact on the seabed.

An alarming report was drawn up in Corsica and Sardinia, two of the largest lobster fisheries in Europe, where there was a marked decline in catches between 1954 and 2008. In Corsica, while 300 tonnes of lobsters were fished in the 1950s **, only 61 tonnes on average were fished over the past two years. In northern Sardinia, catches decreased by 70% between 1976 and 2001.

It is important to remember that for the corsican fishing sector, lobster generates an annual revenue of more than 4 million euros. Lobster fishing alone accounts for up to 70% of the professional island fishing income. Knowing the strong economic benefits generated, a real expectation in terms of controlling lobster raising emanates from sea professionals. This scientific advance could thus ensure the survival of corsican artisanal fishing economy or even contribute to its development, while perpetuating a centuries-old heritage activity.

This breakthrough is now paving the way for compensation methods for fishing activity in order to preserve the presence of lobster in its natural species range. A transfer of individuals could also be considered at European level for the restoration of degraded populations (with the necessary genetic precautions). The challenge of preserving biodiversity is at the heart of the discussions which have strongly mobilized scientists from the University of Corsica and the CNRS.

Economically, controlling lobster raising could help stem the declining catches in Europe due to overfishing. The Stella Mare laboratory is also studying the possibilities of industrial valorization of the shell of crustaceans via biotechnologies (production of chitosan for example, a biopolymer with multiple medical virtues).

This exceptional success once again materializes the platform's desire to transform research into wealth: by promoting eco-responsible fishing and sustainable aquaculture, enhancing and diversifying production from different marine species, managing a reasonable use and exploitation of resources.

The raising of juvenile lobster testifies to the scientific quality of the public research carried out by Stella Mare, in close collaboration with corsican fishermen and aquaculturists. The ambition set from the start of the platform is once again becoming a reality: to provide research inducing cutting-edge innovations in touch with major societal challenges leading to a sustainable and smart exploitation of our bioresources.

"Stella Mare's approach can serve as a model in Europe."

Henri MALOSSE, member of the European Economic and Social Committee (EESC), former president of the EESC from 2013 to 2015

The Stella Mare platform (University of Corsica/CNRS) is located in Corsica, an island in the heart of the Mediterranean, in Europe.

"This laboratory has been developed as a real 21st century marine platform. Nowadays, all those located in Europe are over a century old. The Stella Mare initiative is a sign of a renewed vision of the marine environment."

Françoise GAILL, Emeritus Research Director at the CNRS and former INEE Director and scientific advisor to the INEE, (INEE: the CNRS's Institute of Ecology and the Environment)

STELLA MARE: A BEACON FOR THE BLUE ECONOMY IN THE MEDITERRANEAN

Created in 2011 under the aegis of the University of Corsica, the Stella Mare scientific platform, based near Bastia, in Corsica, an island at the heart of the Mediterranean, specialises in marine and coastal ecological engineering. By bringing together researchers and professionals from the marine discipline for the sustainable management of fisheries resources, its research programmes are innovating in the field of fishing, aquaculture and ecological restoration at a European scale.

It is the flagship of the University of Corsica in the field of marine and coastal environment engineering. Since its inauguration on 11 April 2011, the Stella Mare 3514 (Sustainable Technologies for Littoral Aquaculture and Marine Research) Mixed Services Unit has focused its research and development work on the monitoring and management of fisheries and coastal resources in the Mediterranean. Certified by the CNRS (French National Centre for Scientific Research) in June 2011, this scientific platform joined up with the Institute of Ecology and Environment (INEE) as part of the University of Corsica's research dynamic for efficient and sustainable environmental management.

With nearly 17,000 species documented, the Mediterranean Sea is home to 7.5% of the world's marine fauna and is a real biodiversity hot-spot. However, the impact of human activities

and climate change are subjecting this area to strong pressures that are endangering its ecosystem through habitat degradation, overfishing and the disappearance of certain species.

In this context, where the riches of the sea and this unique environment must be managed as a precious heritage, Stella Mare is working on reconciling the preservation of the natural environment and the exploitation of marine resources with an innovative approach on a European scale. Its scientific approach is built around three main pillars: research, technology transfer to professionals and raising public awareness, particularly among the younger generation.

CNRS INNOVATION MEDAL 2021

Professor Antoine Aiello, director of the Stella Mare Platform (University of Corsica/CNRS) is the national winner of the CNRS Innovation Medal for 2021. The Innovation Medal of the French National Centre for Scientific Research (CNRS) honours women and men whose exceptional research has led to a significant technological, therapeutic or social innovation, enhancing French scientific research. The CNRS is one of the most renowned French public research institutions in the world.

This recognition pays tribute to the scientific excellence of the research carried out at Stella Mare, the technological transfer carried out with local stakeholders, and the societal benefits of the results and tangible applications. The award of the CNRS innovation medal distinguishes the quality of the work of an entire team.

"What has been initiated on this platform serves as an example and presents Corsica as a pilot region for the European blue economy policy in the years to come."

Henri MALOSSE, member of the European Economic and Social Committee (EESC), former president of the EESC from 2013 to 2015

A CUTTING-EDGE TECHNOLOGY

STELLA MARE

On the Marana lagoon, near Bastia, in Corsica, an island in the heart of the Mediterranean, in Europe, the Stella Mare technology centre, inaugurated 4th September 2015, houses more than 1,600m² of laboratories, aquaculture hatcheries and study facilities. Unique for its technical nature, this innovative scientific facility has been custom-designed both to respect the environment and to implement vast Research and Development (R&D) programmes on a professional scale. It is within this vast, state-of-the-art building that the platform's scientific teams are paving the way for the sustainable management of fisheries and coastal resources in the Mediterranean.

In close consultation with maritime professionals, the UMS Stella Mare focuses its research work on three major missions to preserve fishing activities while offsetting the human impact on the marine environment:

- promote environmentally-responsible fishing and sustainable aquaculture,
- to develop and diversify their production of species from the Corsican littoral,

- manage natural resources for sustainable exploitation and maintenance of marine biodiversity.

Around fifty engineers, technicians, research teaching staff and computer scientists are involved in the Research and Development (R&D) programmes conducted by Stella Mare. These teams carry out in-depth studies which consist in particular in assessing the natural stocks of Corsica, analysing the interactions within the ecosystem, controlling the reproduction and breeding processes of different local species and restoring populations or habitats degraded by human action in the marine environment.

Specific work is being carried out on the purple sea urchin (*Paracentrotus lividus*), the flat oyster (*Ostrea edulis*), the lobster (*Homarus gammarus*), the denti (*Dentex dentex*) and endangered or vulnerable species, such as the European spiny lobster (*Palinurus elephas*), the corb (*Sciaena umbra*) or the giant limpet (*Patella ferruginea*), of which Corsica remains one of the last deposits in the world. (See below)

The technological innovations developed in the Stella Mare laboratories aim to lay the foundations of a knowledge-based economy, shared between the world of research and the maritime professionals. The objective is to develop a new, more sustainable blue economy model by moving from a logic of taking from the ecosystem to a real culture made possible by the control and management of species.

CORSICA: A PILOT REGION IN EUROPE IN THE FIELD OF MARINE ECOLOGY

The concrete progress achieved by the platform positions Corsica as a pilot region in Europe in the field of marine ecology. As part of the work carried out on the blue bioeconomy, Professor Antoine Aiello, director of Stella Mare, was thus appointed as an expert to the European Economic and Social Committee (EESC) in July 2019. That same year and in 2020, two delegations from the European Union visited Stella Mare to discover this work on value creation based on the intelligent and sustainable use of fisheries resources.

"Stella Mare is paving the way for the fishing professionals of tomorrow."

C  rard ROMITI, fisherman and president of the regional and national committees for maritime fisheries and marine farming in France

A TRANSFER OF TECHNOLOGY TO MARITIME PROFESSIONALS

The return of this scientific research to the territory is achieved through a transfer of technology to maritime professionals, fishing professionals, aqua-culturists and environmental managers who acquire new skills in the knowledge of the marine environment and species. Since the creation of the platform, this work has enabled the breeding of new local species in aquaculture, the maintenance of overexploited natural stocks, the preservation of threatened species and the diversification of the economic market for fishing and aquaculture professionals.

Stella Mare's work also extends to the ecological restoration of populations or environments degraded by humans. Thus, within the framework of a programme carried out with the island's four governing bodies and the Corsican Regional Committee for Maritime Fisheries and Aquaculture (CRPMEM), ecological restoration of sea urchin populations overexploited by fishing (recreational and professional) has been undertaken on several sites. The aim of this programme is to support the renewal of natural sea urchin stocks to encourage a return to the

initial state of degraded areas and maintain sea urchin fishing activity in Corsica. In the same way, controlling the reproduction of the European flat oyster allows tests to be carried out on the use of this organism as a bio-purifier to clean up habitat environments (Bastia 'old port' marina, aquaculture farm in Ajaccio, Corsica). Finally, controlling the reproduction of the giant limpet will help maintain biodiversity by restoring the extinct populations of this endangered species in the Mediterranean.

The impact of this scientific work on the territory is directly visible. The programme carried out on the flat oyster bears witness to this: by controlling the cultivation of a species that occurs naturally in Europe and has been exploited since antiquity in Corsica only by harvesting (Diana lagoon on the eastern coast of Corsica), which has depleted its natural stocks. The species present in Corsica also has specific resistance to certain parasites which decimated it in Europe in the 1970s and which was replaced by an imported Japanese oyster (hollow oyster) controlled in aquaculture and itself currently decimated by the herpes virus.

This control of flat oyster culture would allow an economic rebound in the Corsican and French oyster industry, as well as the maintenance of a natural stock that is clearly decreasing.

KEY FIGURES FOR FISHING IN CORSICA

- 7.5% of the world's marine fauna sheltered in the Mediterranean
- 180 fishing skippers in Corsica
- 1000 km of coastline
- 43 tons of fish caught per year in Corsica for a turnover of 1 000 000  
- 500,000   sales of purple sea urchins for 30 fishermen
- 7 tons of lobster caught, turnover of 350 000   /year
- 70    / kg selling price of the European spiny lobster (= 31    / lb)
- Rarefaction of European spiny lobster,    4 million, 70% of fishermen's income
- 61 tonnes of European spiny lobster fished in 2019-2020 in Corsica against 300 tonnes in the 1950s
- 80% of Corsica's aquaculture production is exported

AWARENESS OF THE MARINE ENVIRONMENT

In parallel with these various research activities, Stella Mare is pursuing another long-term mission: raising awareness of the marine environment. The scientific platform has developed educational programmes for the general public and school children. Through the walls of the aquariums and the many portholes in the aqua-labs, visitors to Stella Mare can discover the richness of the island's ecosystem and witness science in action through the species under observation in the tanks.

Every year, hundreds of school children from all over Corsica visit these laboratories and learn about the exceptional biodiversity that surrounds them and the innovative solutions developed to mitigate the damage caused by human activity.

Anxious to pass on this knowledge to as many people as possible, the Stella Mare platform has established a close partnership with the Academy of Corsica and a Permanent Centre of Initiatives for the Environment U Marinu, which has been awarded the UNESCO label for sustainable development, with the aim of raising awareness among future generations of the issues involved in preserving and enhancing the natural marine heritage in the Mediterranean.

"In addition to research and technology transfer, the platform enables young people to be trained for jobs directly related to the environment and the marine environment. This is essential both to ensure the continuity and arrival of new professionals and to educate and raise awareness among new generations. »

Henri FRANCESCHI, President of the Corsican fish farmers' union
"Mare & Stagni" since 2002

RESEARCH PROGRAMMES

EUROPEAN SPINY LOBSTER

In 2021, after only three months of experiments, researchers and engineers of the research center succeeded in growing juvenile European spiny lobster (*Palinurus elephas*). Stella Mare becomes one of three laboratories in the world to achieve this scientific and technical prowess. Present from Norway to Mauritania and in many area of the Mediterranean, the European spiny lobster is classified as "vulnerable" species in the red list of threatened species of the International Union for the Conservation of Nature (IUCN). Its high selling price is the result of relative scarcity, confirmed by the continued sharp decline in stock in European Union fishing areas. This major scientific breakthrough has an ecological, economic and heritage stake for Corsica and beyond: Preservation of biodiversity, diversify and maintain fishing activity (a centuries-old heritage activity in Corsica), while protecting the presence of the species in its range; transfer of individuals on a European scale for the fishery restoration of degraded stocks (with the necessary genetic precautions); helps stem the decline in catches in Europe due to overfishing; recycling and recovery of crustacean shells are of interest to biotechnology companies

THE CORB (MEAGRE)

The corb (*Sciaena umbra*) has been studied since 2014 under the remit of the Stella Mare platform. Subject to a moratorium banning recreational fishing in France since 2013, this emblematic Mediterranean coastal marine fish is a strictly protected species and is on the International Union for Conservation of Nature (IUCN) red list. The Stella Mare researchers' project focuses on improving knowledge about this relatively unknown species. With the aim of conserving the corb, the scientists, who have mastered the reproduction and breeding of this species through the development of specific procedures, anticipate the eventual restoration of the declining populations.

THE FLAT OYSTER

Since 2013, the Stella Mare team have been working on the domestication of the flat oyster (*Ostrea edulis*) in the Diana lagoon on the eastern coast of the island. After four years of experimentation with oyster farmers, the researchers and engineers have succeeded in mastering the reproduction of these species and in raising these oysters to maturity. The scientists are now cultivating flat oyster spat in the natural environment, produced in the laboratory from brood stock from the natural environment. This research programme thus meets a threefold challenge: to offer a new aquaculture resource, to revive the economic activities that depend on it and to protect an identity species that is part of Corsica's natural heritage. Although it currently represents less than 5% of oyster production in France, the flat oyster also appears to be an alternative to the hollow oyster, which is less resistant and faces significant mortality due to the proliferation of the herpes virus. Its taste potential is also recognised. The flat oyster has won several gold medals at the General Agricultural Competition, Paris.

THE PURPLE SEA URCHIN

Faced with the decline of purple sea urchin (*Paracentrotus lividus*) populations on the Mediterranean coast and in Corsica, Stella Mare scientists launched a research programme in 2010 to gain a better understanding of this species. The researchers found that overexploitation, habitat degradation, human predation and pollution have made this species vulnerable, to the point where economic pressure now exceeds its natural capacity for renewal. After two years of research, the marine platform teams have succeeded in mastering the reproduction cycle of these echinoderms. The aim is to compensate for these declining resources in order to ensure the survival of the fishery. For the first time in 2018, sea urchins reproduced at Stella Mare from spawners from the Corsican coastline have thus returned to the natural environment at several restoration sites chosen in collaboration with the fishing professionals. Beyond the ecological aspect, there is a considerable stake for the local economy. The turnover from the sale of sea urchins in Corsica represents 500,000 euros per year for about thirty fishermen.

DENTI

Since 2012, the domestication of the Denti (*Dentex dentex*), an emblematic Mediterranean coastal fish, has been part of Stella Mare's Research and Development (R&D) programmes. Largely fished by local and recreational fishing, the denti is the only sparid species classified as "vulnerable" in the Mediterranean by the International Union for Conservation of Nature (IUCN). The aim of this scientific project is to contribute, in collaboration with fish farmers, to the sustainable management of this resource with high economic potential. Each year, around 43 tonnes of denti are fished on the Corsican coast for a turnover of almost one million euros. In addition to recommending protection measures to regulate fishing, the work of Stella Mare has made it possible, since 2015, to control its reproduction. Researchers are currently studying its diet and reproduction conditions. In the long term, their ambition is to restore denti populations on the Corsican coast using stocks produced at Stella Mare.

LOBSTER

The European lobster (*Homarus gammarus*) is at the heart of a Research and Development (R&D) programme implemented at Stella Mare. Since 2012, its teams have been studying its genetics and behaviour in the natural environment as part of a project to diversify the artisanal fishing of large crustaceans in Corsica. In 2015, the scientists succeeded in controlling the reproduction of this species. They are now focusing their research on juvenile rearing techniques with the aim of creating fishing zones dedicated to fishing professionals so that fishing pressure on the lobster species can be reduced. As of 2018, the first releases of juveniles into the natural environment have been carried out on an experimental basis in a coastal area south of Bastia within suitable habitats. Through this programme, Stella Mare hopes to participate in the diversification of coastal fishing by creating a new demand for this crustacean, which is currently much less targeted by professionals than the highly prized European spiny lobster, which is becoming rarer due in particular to large-scale harvesting.

THE GIANT LIMPET

The giant limpet (*Patella ferruginea*), which is highly threatened with extinction, is the subject of in-depth studies at Stella Mare, which consist in particular of assessing the natural stocks and restoring this species, which is banned from fishing and of which Corsica remains one of the last remaining beds on a global scale. Its numbers are particularly low in the marine environment as a whole. The platform's work currently consists of learning more about the behaviour of this protected species and its diet. The aim of these studies is to determine the local resources for feeding the larvae of juveniles, once a reproduction procedure has been developed by the researchers. This work is an essential precursor for pursuing the objectives of this programme: to proceed with the ecological restoration of this threatened species throughout the Mediterranean basin.

BEHAVIOURAL MONITORING OF SPECIES

As part of a behavioural modelling programme, the Stella Mare teams are carrying out experiments to monitor species in the natural environment in real time (lobster, denti, sea urchin, spider crab, corb). Using connected devices, sensor and transmitter networks, and underwater monitoring techniques, this programme has enabled the acquisition of new skills in the field of information collection. The new knowledge gained from this data has led Stella Mare scientists to develop behavioural simulation models of species and has resulted in two invention disclosures.

ECOLOGICAL RESTORATION THROUGH THE CONSTRUCTION OF ARTIFICIAL REEFS

Faced with the erosion of marine biodiversity and the constant decrease in exploitable resources, the Stella Mare platform has launched a programme that proposes several ecological engineering solutions based on the installation, maintenance or natural recruitment of living organisms, aimed at supporting fishing activities and improving the quality of man-made environments. This Research and Development (R&D) project consists of improving biological productivity for fishing and preserving fisheries resources by offering additional and adapted refuge habitats for species of economic interest in poor areas or areas degraded by coastal development. It concerns the design of specific habitats for the various species studied within the other Stella Mare programmes, but also the creation of spawning grounds and nurseries aimed at maintaining local marine biodiversity and, in particular, species subject to economic or recreational exploitation. This programme also envisages the restoration of the environmental quality of man-made environments through bio-purification.

Thus, a pilot project of natural depollution has been undertaken from 2019 with the immersion of metallic cages containing several hundred flat oysters in the Old Port of Bastia in Corsica. This experiment, which is unprecedented on the scale of the Mediterranean, proposes to "bio-purify" the port by using the eco-systemic function of biological filtering of the flat oyster (produced in Stella Mare), which, by capturing the pollutants contained in the sea water, will accumulate them in its flesh and its shell. In the long term, the objective is to evaluate the number of individuals to be used and to evaluate the rate of depollution of a basin, in order to propose rapid solutions to deal with accidental or recurrent pollution that is not managed in the ports.

INTEGRATED MULTI-TROPHIC AQUACULTURE PROJECT (IMTA)

Integrated multi-trophic aquaculture (IMTA) is a practice that contributes to better environmental management while increasing the economic benefits for aquaculture producers. It is based on the concept of recycling, combining the farming of various complementary species from different links in the food chain rather than producing a single species (monoculture). The aim is to recreate an ecosystem in which food residues, waste, nutrients and by-products from one species are recovered and converted into fertiliser, food and energy for the growth of other species. In this context, the AIMT programme at Stella Mare aims to test the natural capacity of certain species produced within the platform and those having different functional roles in the trophic chain: the lobster (carnivorous predator), the flat oyster (filtering particles present in the water column), the sea urchin (plant grazers), and macro-algae (using nutrients for their growth). An initial, very encouraging test carried out with only lobsters on a marine farm in Ajaccio, Corsica, led to a much more ambitious FEAMP (European Maritime Affairs and Fisheries Fund) programme involving all of the above species.

KEY DATES

STELLA MARE

2005 Creation of the scientific advisory council of the University of Corsica

2007 Study trip to Crete and discovery of the laboratory of researcher Pascal Divanach (Hellenic centre for marine research)

2009 Approval of the project for the creation of a marine platform by the Mediterranean Sea Centre (Approved as a competitiveness cluster with a global vocation, it brings together and supports start-ups, SMEs, large groups, research and training organisations)

2010 Purchase of land by the University of Corsica on the lagoon of La Marana, near Bastia in Corsica

2011 Inauguration of the Stella Mare advanced base
Accredited by the CNRS (French National Centre for Scientific Research)

2012 Controlling of purple sea urchin reproduction

2013 Accredited with the Aquimer competitiveness cluster (a resource for companies in the aquatic production sector to help them develop and innovate)

2015 Inauguration of the Stella Mare technology centre
Controlling the reproduction of dent and lobster

2017 Management of flat oyster reproduction

2019 Management of corb reproduction

2019 Appointment of Antoine Aiello, Director of Stella Mare, as an expert to the European Economic and Social Committee (EESC) for an exploratory opinion on the blue bioeconomy
EESC working group on the blue bio-economy visits Stella Mare

2020 Visit to Stella Mare of the EESC Mission, European Parliament and European Commission (DG MARE)

2021 National Innovation Medal of the CNRS (French National Centre for Scientific Research)
Growing European spiny lobster juveniles

ABOUT THE UNIVERSITY OF CORSICA PASQUALE PAOLI

The University of Corsica Pasquale Paoli is located on an island of 340 000 inhabitants in the heart of the Mediterranean, in Europe. Founded in 1765, then reopened in 1981, the University of Corsica is a training and research structure anchored in its territory, in direct contact with the major local, national and international issues. With a deliberately multidisciplinary range of courses, the institution has chosen to concentrate its research on niches of excellence recognised at the highest level.

The scientific identity of the University of Corsica is based on multidisciplinary projects approved by the National Centre for Scientific Research (CNRS), one of the most renowned French public research institutions in the world.

The projects combine basic and applied research with a view to territorial development and lead to concrete achievements with high added value, such as the Stella Mare marine platform and the Myrte Paglia-Orba solar platform.

<https://stellamare.universita.corsica>

<https://myrte.universita.corsica>

<https://paglia-orba.universita.corsica>

Due to its exceptional Mediterranean environment, research at the University of Corsica also focuses on the management and development of fresh or marine waters, biodiversity, aquaculture and sustainable fishing; the production and storage of renewable solar and hydrogen energies; the development of Mediterranean natural resources, aromatic and medicinal plants, heritage agri-food products (e.g. olive oil, citrus fruit, honey); sustainable development; the study of wildfires for the protection of people, property and the environment and land use planning.

But equally focus on modelling and artificial intelligence for territorial development and establishment of a smart city concept; virology, epidemiological and genetic surveillance and research on infectious diseases in the Mediterranean, both human and animal.

Or the modelling of the economic development of territories; comparative law in the Mediterranean, digital law. The University of Corsica also plays an essential role in the development, protection, promotion and transmission of the identity, language, culture, heritage and crafts of its territory.

In terms of training, the University of Corsica Pasquale Paoli offers more than 100 multidisciplinary diplomas at undergraduate, bachelor, licence, post-graduate and doctorate levels, delivered by 8 faculties, institutes and schools. The constant interest in the integration of its 5,000 students is based on training courses with a high professional content, in line with the major development issues of its territory: digital, entrepreneurship, international trade, environmental engineering and renewable energies, audio-visual and communication, economics and business management, sustainable tourism, law, teaching, literature, languages, art, civil engineering, health, etc.

The University of Corsica is strongly committed to international mobility and encourages its students to develop a genuine culture of mobility. More than 60 different nationalities are welcomed on campus.

The University of Corsica also organises or hosts high-level international meetings throughout the year, in particular at its Institute of Scientific Studies in Cargèse (University of Corsica/CNRS/University of Côte d'Azur), where 2000 participants from all over the world meet each year.

Through the initiative of the University of Corsica, 28 island universities from all over the world (Mediterranean, Northern Europe, Atlantic Europe, Indian Ocean, Africa, Caribbean, North America, Oceania and Asia) have joined forces within the RETI international network, in order to create a common space for scientific and academic exchanges from the islands and about themes associated with insularity.

WWW.UNIVERSITA.CORSICA/EN

ABOUT THE CNRS

The French National Center for Scientific Research is one of the most recognized and renowned public research institutions in the world. For more than 80 years, it has continued to attract talent at the highest level and to nurture multi-disciplinary and interdisciplinary research projects at the national, European and international levels. Geared towards the public interest, it contributes to the scientific, economic, social and cultural progress of France.

The CNRS is above all 32,000 women and men, more than 1,000 laboratories in partnership with universities and other higher education institutions bringing together more than 120,000 employees and 200 professions that advance knowledge by exploring the living world, matter, the Universe, and the functioning of human societies. The CNRS ensures that this mission is carried out in compliance with ethical rules and with a commitment to professional equality. The close relationship it establishes between its research missions and the transfer of acquired knowledge to the public makes it today a key player in innovation in France and around the world. Partnerships with companies are at the heart of its technology transfer policy, and the start-ups that have emerged from CNRS laboratories bear witness to the economic potential of its research.

The CNRS provides also access to research findings and data, and this sharing of knowledge targets many audiences: scientific communities, the media, decision-makers, economic players and the general public.
